

MODERN
RADIOLOGY
eBook

Nuclear Medicine

ESR EUROPEAN SOCIETY
OF RADIOLOGY

/ Preface

Modern Radiology is a free educational resource for radiology published online by the European Society of Radiology (ESR). The title of this second, rebranded version reflects the novel didactic concept of the *ESR eBook* with its unique blend of text, images, and schematics in the form of succinct pages, supplemented by clinical imaging cases, Q&A sections and hyperlinks allowing to switch quickly between the different sections of organ-based and more technical chapters, summaries and references.

Its chapters are based on the contributions of over 100 recognised European experts, referring to both general technical and organ-based clinical imaging topics. The new graphical look showing Asklepios with fashionable glasses, symbolises the combination of classical medical teaching with contemporary style education.

Although the initial version of the *ESR eBook* was created to provide basic knowledge for medical students and teachers of undergraduate courses, it has gradually expanded its scope to include more advanced knowledge

for readers who wish to 'dig deeper'. As a result, *Modern Radiology* covers also topics of the postgraduate levels of the *European Training Curriculum for Radiology*, thus addressing postgraduate educational needs of residents. In addition, it reflects feedback from medical professionals worldwide who wish to update their knowledge in specific areas of medical imaging and who have already appreciated the depth and clarity of the *ESR eBook* across the basic and more advanced educational levels.

I would like to express my heartfelt thanks to all authors who contributed their time and expertise to this voluntary, non-profit endeavour as well as Carlo Catalano, Andrea Laghi and András Palkó, who had the initial idea to create an *ESR eBook*, and - finally - to the ESR Office for their technical and administrative support.

Modern Radiology embodies a collaborative spirit and unwavering commitment to this fascinating medical discipline which is indispensable for modern patient care. I hope that this *educational* tool may encourage curiosity and critical thinking, contributing to the appreciation of the art and science of radiology across Europe and beyond.

What is Nuclear Medicine

Nuclear Medicine is the practice of using small quantity of unsealed radioactive sources to diagnose, monitor disease and provide targeted therapy.

Most imaging modalities, such as computed tomography (CT) or magnetic resonance imaging (MRI)

demonstrate body anatomy. Nuclear medicine is one of the few imaging modalities that demonstrate body physiology, so called 'functional' imaging. For example, a whole-body bone scan shows bone turnover. This allows nuclear medicine to have a wide range of applications across many body systems, and pathologies.

/ Terminology

- / A radiopharmaceutical combines a **radio-nuclide** and **pharmaceutical**.
- / A **radionuclide** is an unstable form of an element that emits radiation from its nucleus as it decays to a more stable form. The emitted radiation from the patient is used to create the image in nuclear medicine. Elements used for diagnostic imaging usually either emit beta particles (positrons or electrons) or gamma rays.
- / **Pharmaceuticals** have properties that help to target specific organs/tissues or molecular pathways.
- / Technetium-99m is the most used radionuclide in nuclear medicine and can be combined with a wide range of pharmaceuticals which enables targeting of different organs and physiological processes.

FIGURE 2

NM Imaging Modalities

/ Gamma Camera

1. Radionuclides decay releasing gamma photons.
2. Collimators are made of lead with holes. These only accept gamma photons that travel parallel to the collimator holes.
3. A scintillation crystal is fluorescent; i.e., when a gamma photon interacts, it releases light photons. The amount of light is proportional to the deposited energy of the gamma photons.
4. Photomultiplier tubes detect the light photons from the crystal and convert these into an electrical signal.
5. A computer processes the electrical signal to calculate the energy of the received photons and their x, y coordinates within the patient to form the final images.

/ Planar Imaging

- / 2D imaging technique.
- / Typically, anterior and posterior views.
- / Oblique views - depending on clinical indication.
- / Commonly used applications include bone, kidneys, thyroid, hepatobiliary and gastrointestinal tract imaging.

Static

- / Radiopharmaceutical is injected intravenously/ingested, and images are acquired after a certain time period delay called 'uptake time'.
- / The uptake time and scan duration is dependent upon the half life of the radionuclide and the study being performed. E.g., 2-3 hours for a Technetium-99m labelled DMSA

renal scan compared to 4-6 hours for an Iodine-123 thyroid uptake scan.

- / Static imaging is used to gain information about the organ of interest based on size, morphology, intensity and position of radiopharmaceutical uptake.

Dynamic

- / Distribution of radiopharmaceuticals change with time due to their inherent properties.
- / Images are usually acquired immediately post injection with series of frames over time.
- / Time interval between frames varies between different studies.
- / Functional assessment of a system is provided based on radiopharmaceutical distribution over time.

/ SPECT and SPECT/CT Imaging

Single photon emission computed tomography (SPECT) is an extension of conventional gamma camera imaging.

Typically, two gamma camera heads rotate around the patient on a gantry acquiring a series of planar images which are reconstructed into 3D images.

Computed Tomography (CT) images may be acquired alongside SPECT. These permit attenuation correction and localisation of sites of radiotracer uptake in the body.

TABLE 2

Comparison of SPECT and Planar Imaging

/ Positron Emission Tomography (PET) Imaging

PET imaging uses radionuclides that are proton rich (nucleus contains a relatively large number of protons compared to neutrons) and decay by positron emission.

The positron-emitting radionuclide undergoes β^+ decay with a proton converted to a neutron, a positron and a neutrino. The positron (e^+) is the antiparticle of the electron (e^-) with the same mass and electrical charge as the electron. However, the charge is positive.

Positrons travel a short distance through tissue and annihilate with electrons (see Figure 8, page 20).

This annihilation process, produces two photons of 511 kiloelectron volts (keV) energy which travel in opposite directions (at 180° to each other) and are detected by opposed radiation detectors.

The near simultaneous detection of the two photons allows the localisation of their origin to a line joining the detectors which is called annihilation coincidence detection.

/ Bone Scan

Indications:

Oncology (particularly prostate and breast cancer), rheumatology, bone and joint infections, painful joint prosthesis, metabolic bone disease

Route: Administered intravenously

Radiopharmaceutical:

Technetium-99m (^{99m}Tc) labelled bisphosphonates such as (^{99m}Tc)Tc -HDP (hydroxyethylene diphosphonate) or MDP (methylene diphosphonate) which bind to calcium and hydroxyapatite crystals in bone in proportion to local vascularity and osteoblastic activity

Image acquisition:

- / **Anterior and posterior whole body planar:** Acquired 3-4 hours post-injection for optimal concentration of radiopharmaceutical by osteoblasts and clearance from tissues
- / **Dynamic: 3 phases:** selected cases, e.g., infected prosthesis
 - / **Flow phase** (2-to-5 second images obtained for 60 seconds immediately after injection)
 - / **Blood pool phase** (5 minutes after injection)
 - / **Delayed phase** (3-4 hours after injection)

Strengths and limitations:

- / Uptake of Technetium-99m is based on vascularity and osteoblastic activity. Other bone lesions such as infection and trauma can also demonstrate high uptake. Therefore, bone scans are sensitive but nonspecific so correlation with other modalities may be needed.
- / Lytic lesions (e.g., myeloma and certain tumour metastases, e.g., renal cell) may not be visible on bone scintigraphy as bone scans assess osteoblastic activity and these are typically osteoclastic.

Differential Diagnosis of Hyperthyroidism

Thyroid Scintigraphy is the key test for differentiating causes of hyperthyroidism due to different patterns of uptake:

- A. Graves' disease – homogenous increased uptake
- B. Toxic multinodular goitre – multifocal uptake, often heterogenous
- C. Autonomous toxic nodule – uptake in a single, often enlarged, nodule
- D. Subacute thyroiditis – no uptake

A 'cold' focal area with reduced uptake is concerning for a malignant nodule. In these cases, ultrasound is needed to better characterise the nodule and determine whether biopsy is required.

/ Ventilation/Perfusion (V/Q) Scan

Indications:

Diagnosis of acute pulmonary embolism with normal chest radiograph.

Work-up of patients with pulmonary hypertension to determine whether the cause is due to chronic thromboembolic disease.

Quantification of differential lung function preoperatively (for example prior to pneumonectomy in lung cancer patients).

>=< FURTHER KNOWLEDGE

Pregnant patient should be counselled regarding radiation doses. Typically, radiation dose to maternal breast tissue is greater for CTPA compared to V/Q scan; doses to fetus are equivalent.

<!=> ATTENTION

If performing V/Q scan for acute pulmonary embolism, make sure chest radiograph has been performed and reviewed within 12 to 24 hours prior to lung scintigraphy. This is because there are other causes of perfusion defects which can be excluded on chest radiograph such as atelectasis, pneumonia, etc.

TABLE 6

Comparison of V/Q scan and CTPA

Abbreviations: CT pulmonary angiogram (CTPA); pulmonary embolism (PE)

/ Dimercapto Succinic Acid (DMSA) Renal Scan

Indications:

- / Detection of focal renal parenchymal abnormalities including assessment of renal scarring
- / Differential renal function estimation
- / Assessment of horseshoe, solitary or ectopic kidney

Radiopharmaceutical:

- / Technetium-99m labelled-DMSA (2, 3-dimercapto-succinic acid) is protein-bound and removed from plasma, and concentrates in the proximal tubules of the renal cortex

Route: Administered intravenously

Image acquisition:

- / Static planar 2-3 hours post-injection
- / Views: anterior, posterior and 45 degree left and right posterior oblique

Usefulness of the test compared with other imaging modalities:

- / More accurate assessment of divided renal function compared to a renogram (see next section).
- / Pyelonephritis may also be identified as defects and mimic scars.
- / Other imaging modalities such as ultrasound and CT can assess renal size but cannot quantitatively assess function.

/ Renal: Renogram

Indications:

- / Assessment of renal perfusion
- / Evaluation of divided renal function
- / Possible obstruction
- / Assessment of the urinary tract post-surgery, e.g., post pyeloplasty for pelviureteric junction (PUJ) obstruction

Radiopharmaceutical:

- / [^{99m}Tc]Tc- Mercaptoacetyltriglycine (MAG3):
 - / Undergoes both glomerular filtration and tubular excretion
- / [^{99m}Tc]Tc- Diethylene-triamine-pentaacetate (DTPA):
 - / Alternative but less used in clinical practice, undergoes glomerular filtration only

Route: Administered intravenously

Image acquisition:

- / Dynamic planar imaging for 30 minutes
- / Then static images acquired pre-micturition, post-micturition and delayed 2-hours post-micturition
- / Furosemide injected to assess for obstruction – timing varies between institution
- / Computer processing of data to provide time activity curve

/ Nuclear Medicine

Test Your Knowledge

Normal Case

Time activity curve is a representation of the uptake and excretion of the radiopharmaceutical by the kidneys as a graph.

Renogram has three phases:

A - Vascular (flow phase) - shows blood flow and initial uptake of radiopharmaceutical by the kidneys, usually lasts 30 to 60 seconds (yellow arrow)

B - Cortical transit (tissue-function phase) - radiopharmaceutical concentrates in renal tubules, peaks at 3-5 minutes (pink arrow)

C - Excretory (drainage phase) - downslope in the renogram indicating excretion of radiopharmaceutical by the kidneys. It usually starts at 4-8 minutes after radiotracer injection (purple arrow).

Both kidneys show prompt tracer uptake, normal transit, excretion and drainage. The time activity curves are normal. Normal study with no evidence of obstruction.

Test Your Knowledge

Case: Right kidney pelviureteric junction obstruction

CT abdomen and pelvis demonstrated right sided hydronephrosis (yellow arrow). Normal appearance of left kidney (green arrow).

On the renogram there is delayed uptake, cortical transit, excretion and limited drainage of the right kidney demonstrated by the flattened amplitude of

the time-activity curve (green curve, pink arrow). Appearances are in keeping with a very high-grade/ near complete obstruction. The left kidney shows prompt tracer uptake, normal transit, excretion and drainage (red curve, purple arrow). The blue curve represents tracer within the urinary bladder.

Test Your Knowledge

Case: Right kidney pelviureteric junction obstruction

A) In the initial vascular (flow) phase - radiopharmaceutical within the abdominal aorta (red arrow) and left kidney (yellow arrow). No activity demonstrated in the right kidney (green arrow).

B) Cortical transit (tissue-function) phase - radiopharmaceutical concentrates in renal tubules of the left kidney (yellow arrow). Faint rim of cortical uptake around the grossly distended pelvis of the right kidney (green arrow).

C) Excretory (drainage) phase - radiopharmaceutical demonstrated within the left renal pelvis (yellow arrow), ureter (yellow arrow) and bladder (purple arrow) in keeping with excretion of radiopharmaceutical by the left kidneys. Increasing activity within the right kidney cortex (green arrow) but no radiopharmaceutical within the renal pelvis or ureter.

D) Low level activity within the dilated right pelvicalyceal system (green arrow) on the post micturition.

Appearances are in keeping with a very high-grade/near complete obstruction.

Usefulness of the test compared with other imaging modalities:

- / Dynamic test hence useful for assessment of urine passage and check for high-grade obstruction which can lead to obstructive uropathy and nephropathy.
- / CT and MR urogram demonstrate anatomical abnormality but renogram provides functional assessment helping to determine degree of impaired drainage and split function.

/ Myocardial Perfusion Imaging

Indications:

- / To identify the presence, site and grade the severity of coronary artery disease
- / Select patients who will benefit from revascularisation, e.g., PCI/CABG
- / Assess response post revascularisation or medical treatment

Radiopharmaceutical:

- / Technetium-99m labelled Tetrofosmin (Myoview) or Sestamibi - lipophilic cationic agents which passively diffuse and accumulate in the mitochondria of viable myocardial tissue

Route: Administered intravenously

Image acquisition:

- / Two components: stress and rest. Depending on institutions performed on same day or separate days
- / Rest: Imaging 45-60 minutes post radiopharmaceutical injection
- / Stress: Exercise test or pharmaceutical stress agents given prior to radiopharmaceutical. Either adenosine, regadenoson, or dobutamine are used depending on their background medical history and medications.
- / SPECT Imaging
- / Additional CT component acquired for attenuation correction

Pharmaceutical stress agent:

A stress myocardial perfusion scan assesses blood flow to the myocardium under stress.

Stress test can use exercise (e.g., bicycle or treadmill). If patients are unable to exercise, the heart can be stressed by taking a pharmaceutical

stress agents that increases heart rate or dilate coronary arteries like physical exercise.

The table lists the main pharmaceutical stress agents and mechanism of action.

PHARMACEUTICAL STRESS AGENT	MECHANISM OF ACTION
Regadenoson	Specific A2A adenosine receptor agonist Vasodilator (direct)
Adenosine	Nonspecific adenosine receptor agonist Vasodilator (direct)
Dipyridamole	Prevent the intracellular reuptake and deamination of adenosine Vasodilator (indirect)
Dobutamine	β 1- and β 2-receptor agonist Vasodilator (indirect)

STUDIES	USEFULNESS OF THE TEST COMPARED WITH OTHER IMAGING MODALITIES
Myocardial Perfusion Imaging (MPI)	Functional assessment compared to anatomical information gained from coronary angiogram or CT coronary angiogram MPI provides limited quantification of perfusion and limited spatial resolution
PET perfusion imaging (Rubidium-82 or Nitrogen-13)	Better spatial resolution and decreased noise compared to SPECT but not widely available
Cardiac MRI	High spatial resolution, can perform quantification of perfusion, and avoids ionising radiation. Detailed characterisation of myocardial tissue can be performed but expensive and limited availability
CT coronary angiogram	Provides anatomical information by visualising the coronary artery lumen and assessing coronary artery stenosis but does not provide functional information
Stress echocardiogram	Widely available, bedside test, inexpensive, however operator dependent, lack of reproducibility

TABLE 8
Comparison of different cardiac imaging modalities

/ Metaiodobenzylguanidine (MIBG)

Indications:

- / Detection, localisation, staging and follow-up of neuroendocrine tumours: Pheochromocytomas, Neuroblastomas, Carcinoid tumours, etc.
- / Iodine-131 labelled MIBG is used for treatment of certain neuroendocrine tumours

Route: IV slowly over 4 minutes

Radiopharmaceutical:

- / Iodine-123 labelled with MIBG (meta-iodobenzylguanidine)
- / MIBG is an analogue of noradrenaline and guanethidine and enters neuroendocrine cells by an active uptake mechanism via the adrenergic transporters and stored in neurosecretory granules

Image acquisition:

- / Early planar 4 hours post injection
- / Delayed planar 24 hours post injection
- / +/- SPECT/CT at 24 hours

/ DaT Scan

Indications:

- / Diagnosis of Parkinson's disease and other neurodegenerative parkinsonian syndromes (e.g., dementia with Lewy bodies, progressive supranuclear palsy, and multiple system atrophy)
- / Differentiating between dementia with Lewy bodies and other dementias
- / Differentiating between parkinsonism due to presynaptic degenerative dopamine deficiency and other forms of parkinsonism, e.g., drug induced, psychogenic or vascular

Route: Administered intravenously

Radiopharmaceutical:

- / Iodine-123 DaTSCAN (Ioflupane or FP-CIT) administered intravenously
- / Bind to presynaptic dopamine active transporters within the nigrostriatal pathway
- / Loss of nigrostriatal dopaminergic nerve terminals in patients with parkinsonian syndromes. Uptake of the radiopharmaceutical corresponds to the integrity of these transporters

Image acquisition:

- / Imaging is performed 3-6 hours post-injection
- / Patient positioned supine in a headrest
- / Trans axial tomographic slices acquired

/ Nuclear Medicine

Usefulness of the test compared with other imaging modalities:

- / Used synergistically with other tests depending on clinical indication, e.g., MRI brain or FDG PET/CT.
- / Only readily available test to assess for pre-synaptic dopaminergic neuronal loss making it useful for its primary indication.
- / If there is concern over vascular parkinsonism (especially if there are clinical risk factors or unilateral abnormal findings on a DaT scan), an MRI would be helpful to assess for an ipsilateral infarct.
- / MRI or perhaps even FDG PET/CT may be used together with DaT scan when trying to discriminate causes of dementia.

Radiopharmaceutical:

- / Fluorine-18 labelled fluorodeoxyglucose (FDG), Glucose analogue
- / Cyclotron produced
- / Half-life 110 minutes
- / FDG is metabolised to FDG-6-Phosphate. FDG enters cells via GLUT transporters similar to glucose but accumulates intracellularly after initial phosphorylation as it cannot undergo further metabolism. The higher the metabolic activity of the cells, the higher the FDG uptake. Malignant cells increase GLUT and hexokinase activity

Route: Administered intravenously

FIGURE 44

Test Your Knowledge

Image acquisition:

- / Fast 4-6 hours prior to scan - optimise glucose and insulin levels
- / No intense physical exercise 24 prior to scan - reduce muscle FDG uptake
- / Patient should rest in a room for a period of 30 min to 1 hour - reduce muscle FDG uptake
- / Patient should void before start of images - reduced FDG concentration in urinary bladder
- / Imaging is performed 60 minutes post-injection
- / Images acquired depending on protocols; either whole body (From the top of the head through the feet), torso imaging (from the top of the head/base of skull to mid-thigh)
- / Combined with low dose CT for attenuation correction and localisation

FDG PET/CT: EANM procedure guidelines for tumour imaging: version 2.0, 2015

Blood glucose and insulin

- / Both glucose and FDG are actively transported into cells, so glucose levels in blood will affect the uptake of FDG.
- / High blood glucose levels will result in lower uptake of FDG.
- / High insulin levels would cause increased FDG uptake into muscles and subcutaneous tissue
- / It is important that blood glucose levels are within a normal range before [^{18}F] FDG administration.
- / Patients must fast for 4-6 hours prior to a FDG PET scan.
- / The preparation for diabetic patients is complicated and depends on the type of medications and if on insulin.
- / A recent medical history is vital prior to imaging.

Factors affecting SUV	blood glucose insulin levels at time of injection time period between FDG administration and scanning
High SUV	most high-grade malignancies, infectious and inflammatory processes
Low SUV	specific malignancies (prostate, hepatocellular carcinoma, lung adenocarcinoma spectrum lesions, neuroendocrine tumours) and histological subtypes (low grade, mucinous/lobular tumours), smaller tumours (particularly below 6 mm)

TABLE 9
SUV

Normal Case Example

Normal Physiological Uptake

- / **Brain:** Intense FDG uptake as glucose is main substrate for metabolism.
- / **Urinary tract** (kidneys, ureters and bladder): High uptake as excretion route is renal.
- / **Myocardium:** variable and dependent on insulin/glucose levels and the patient's fasting status (low post fast). Myocardium usually prefers fatty acid for its metabolism.
- / **Gastrointestinal tract:** Uptake is variable, diffuse mild to moderate uptake is normal. Metformin can increase FDG uptake.
- / **Liver:** Low/moderate, diffuse homogeneous uptake.
- / **Salivary glands, tonsils, thyroid:** Mild to moderate symmetric uptake.
- / **Muscles:** FDG uptake is usually low. FDG accumulation in muscles can be increased following exercise and with elevated insulin.
- / **Brown fat:** Metabolically active adipose tissue usually located within supraclavicular, axillary, mediastinal and paravertebral regions, observed if the patient is cold and more so in younger patients.

PROS +

- Anatomical and functional imaging on a single study (however the CT component is a low-dose study compared to standard CT imaging)
- Detects metastatic disease that would have been missed on conventional CT/MRI Imaging which is crucial for management decisions

CONS -

- False positives in oncology scans: infectious and inflammatory processes, and sarcoid-like reaction in malignancy, ureteric activity mimicking lymph nodes
- False negatives: Histology (low grade, necrotic or mucinous tumours, certain cancers such as prostate, hepatocellular carcinoma), small tumours

TABLE 11
Pros and Cons of FDG PET/CT

/ PSMA PET Scan

Indications:

- / Staging of high-risk primary prostate cancer prior to prostatectomy
- / Detectable PSA post-prostatectomy in the setting of persistent elevation of PSA (≥ 0.2 ng/ml) post prostatectomy, to assess for residual or otherwise occult disease, not identified pre-operatively
- / Localisation of disease in biochemical recurrence after radical prostatectomy, and radical radiotherapy if it will affect subsequent patient management decisions
- / Patient selection for Lutetium-177 labelled PSMA radionuclide therapy in metastatic castration-resistant prostate cancer

Route: Administered intravenously

Radiopharmaceutical:

- / Prostate-specific membrane antigen (PSMA) a trans-membrane glycoprotein that is expressed on the cell surface in normal prostate tissue
- / PSMA expression is increased in prostate cancer especially higher-grade tumours
- / PSMA can be labelled with Gallium-68 (Ga68), a positron emitter. There are radiotracers such as Fluorine-18 which can be labelled to PSMA with similar biodistribution but difference in binding affinities and nonspecific uptake.
- / Eluted from a Germanium-68 (68Ge)/68Ga generator
- / Half-life of 68 minutes

Image acquisition:

- / Imaging is performed approximately 45–75 minutes after radiopharmaceutical administration
- / PET images acquired from the pelvis to the head to minimise misregistration between the CT and PET components of the study due to filling of the bladder during acquisition

/ Nuclear Medicine

Case: Prostate cancer recurrence with lymph node and osseous metastatic disease

76 years old male. Rising PSA 129 post previous radiotherapy for prostate cancer.

PSMA avid disease in the prostate (green arrow) with small volume right inguinal and pelvic nodal disease (purple arrow), as well as multiple bone metastases (yellow arrow).

Usefulness of the test compared with other imaging modalities:

Pelvic MRI is superior to other imaging modalities for local regional staging of prostate cancer.

[68Ga]Ga- PSMA PET/CT allows comprehensive metastatic disease assessment of the prostate, lymph nodes, soft tissues and bones. High sensitivity of PSMA PET, allows identification of small-volume disease, compared with conventional imaging.

Other PET radiopharmaceuticals for Prostate cancer include Fluciclovine, and radiolabelled Choline (Fluorine-18 or Carbon-11). Evidence suggest PSMA PET has superior diagnostic performance compared to the above pharmaceuticals.

False negative - 10% prostate cancer can be PSMA negative.

False positives:

- / Infection/inflammatory process, e.g., prostatitis
- / Bone conditions, e.g., fracture, Paget's disease, fibrous dysplasia
- / Benign tumours, e.g., adrenal adenoma
- / Other malignancies expressing PSMA, e.g., breast, lung, colorectal

/ DOTATATE PET Scan

Indications:

- / Neuroendocrine tumours (NET) localisation of primary tumour and detect sites of metastatic disease (staging)
- / Follow-up imaging to detect residual, recurrent or progressive disease (restaging)
- / Selection of patients for somatostatin receptor-targeted peptide receptor radionuclide therapy
- / Also used for assessment of pheochromocytoma, paraganglioma, neuroblastoma, and meningioma

Procedure guidelines for PET/CT tumour imaging with ^{68}Ga -DOTA-conjugated peptides: ^{68}Ga -DOTA-TOC, ^{68}Ga -DOTA-NOC, ^{68}Ga -DOTA-TATE, 2010

Route: Administered intravenously

Radiopharmaceutical:

- / Somatostatin receptors (SSTRs) are present on the cell surface of neuroendocrine cells
- / DOTATATE is a somatostatin analogue, binds to SSTR type 2
- / Gallium-68 is labelled with DOTATATE. Other pharmaceutical including DOTATOC and DOTA-NOC which have affinity for different somatostatin receptors

Image acquisition:

- / Imaging is performed approximately 45–60 minutes after radiopharmaceutical injection

Normal Case

Normal Physiological Uptake

Related to **specific receptor binding** and **non-specific tissue handling** of the peptide.

- / **Spleen:** Highest intensity physiologic uptake, SSTR expression
- / **Kidneys:** Glomerular filtration, partially reabsorption in the proximal convoluted tubule, resulting in high activity in the collecting system and bladder, retained activity in the renal parenchyma
- / **Pituitary, thyroid and adrenal glands:** SSTR expression
- / **Liver:** Moderate, diffuse homogeneous uptake
- / **Salivary glands:** SSTR expression
- / **GI Tract:** Variable physiologic radiopharmaceutical uptake

Usefulness of the test compared with other imaging modalities:

- / Multiple studies have shown [^{68}Ga]Ga- DOTATATE PET/CT to be more accurate than conventional imaging, including octreotide SPECT/CT and contrast material-enhanced CT, in the diagnosis of low- and intermediate-grade NETs.
- / Most NETs have low uptake on [^{18}F]FDG PET/CT scan. It is used in the staging or restaging (including pre-operative assessments) of selected patients with poorly differentiated high-grade NETs.

/ Take-Home Messages

- / Nuclear Medicine is a specialty allowing functional assessment beyond anatomical information provided by other imaging modalities.
- / A radiopharmaceutical combines a radionuclide and pharmaceutical, enabling targeting of different organs and physiological processes.
- / Three major imaging modalities used in nuclear medicine are planar, SPECT and PET.
- / SPECT and PET imaging can be combined with CT/MRI for attenuation correction and anatomical localisation.
- / Technetium-99m is the most commonly used radiopharmaceutical in planar and SPECT imaging.
- / Fluorine-18 FDG is the most commonly used radiopharmaceutical in PET imaging.

<?> ANSWER

1

What type of radiation is used in Planar and SPECT imaging?

- ☐ Alpha radiation
- ☐ X-ray
- ☐ Ultraviolet
- ☒ Gamma radiation

Planar and SPECT imaging uses gamma radiation. Alpha radiation is used in radiotherapy and certain radionuclide therapies. X-ray is used for conventional radiology imaging techniques including plain film radiography, fluoroscopy and computed tomography. Ultraviolet has no role in imaging studies.

<?> ANSWER

2 What is the half-life of Technetium-99m?

- ☐ 110 minutes
- ☒ 6 hours
- ☐ 68 minutes
- ☐ 8 days

The half-life of Technetium-99m is 6 hours. This makes for a good radiopharmaceutical because it is long enough to be able to transport but not too long that the patient is radioactive for an extended period of time.

3 Technetium-99m is used in the assessment of bone metastasis. Which of the following cancers is [^{99m}Tc]Tc- HDP used in the assessment of bone metastasis?

- ☒ Prostate
- ☒ Lung
- ☐ Renal
- ☐ Thyroid

[^{99m}Tc]Tc- HDP is useful for osteoblastic metastasis such as prostate and breast (can be mixed). Lytic/osteoclastic bone metastases are not evident and may even appear as photopenic regions.

4

36 years old female patient presents with clinical and biochemical symptoms of hyperthyroidism. As part of the investigation, she had a [^{99}mTc]Tc-pertechnetate thyroid scan (see Figure 55). What diagnosis is demonstrated in the study?

FIGURE 55

[^{99}mTc]Tc Thyroid scan

- ☐ Graves' disease
- ☐ Toxic multinodular goitre
- ☒ Autonomous toxic nodule
- ☐ Subacute thyroiditis

There is a rounded, focal tracer activity centred on the mid right lobe of the thyroid. Appearances are keeping with autonomous nodule in the right lobe of the thyroid.

<?> ANSWER

5

Which of the following is an indication for renal DMSA?

- ☒ Assessment of renal scarring
- ☐ Calculation of e-GFR
- ☐ Identify renal obstruction
- ☐ Corticomedullary differentiation

DMSA scans allow detection of focal renal parenchymal abnormalities including assessment of renal scarring. $[^{99m}\text{Tc}]\text{Tc-DTPA}$ is used for eGFR calculation. MAG3 renogram plays crucial role in confirming renal obstruction alongside other imaging modalities such as US and CT. US, CT, and MRI demonstrate the anatomy including corticomedullary differentiation of the kidneys.

<?> ANSWER

10 Which of the following organs demonstrate normal physiological uptake in DOTATATE PET imaging?

- ☐ Brain
- ☐ Heart
- ☒ Spleen
- ☐ Pancreas

Normal physiological uptake in DOTATATE PET scan is related to specific receptor binding and nonspecific tissue handling of the peptide. Spleen demonstrates highest intensity physiologic uptake due to SSTR expression. Other organs with normal physiological uptake include kidneys, pituitary, thyroid, adrenal glands, liver, salivary glands and GI tract.
